This invention relates to a thin film transistor and more particularly to a thin film transistor capable of continuously performing high speed driving. A thin film transistor using a semiconductor film formed on an insulating substrate such as a glass substrate by using semiconductor film forming techniques such as CVD or sputtering is employed as a switching device for driving an active matrix type liquid crystal display device. The thin film transistor is a field effect transistor having an active layer formed from polycrystalline silicon, amorphous silicon, a polycrystalline silicon film having a low concentration of a donor impurity, a polycrystalline silicon film having a high concentration of a donor impurity, or a film of amorphous silicon having a high concentration of an acceptor impurity. A TFT having an active layer of amorphous silicon formed on a glass substrate by a plasma CVD method is known as a typical example of a prior art thin film transistor using a polycrystalline silicon thin film. A TFT has a problem that it has a high OFF-current value. Therefore, it is necessary to use a thin film transistor in which an active layer is made of a polycrystalline silicon thin film to be polycrystallized by a laser annealing process. There is also a problem that a TFT including a gate electrode made of a material having a high resistance such as molybdenum, tungsten, tantalum or titanium has a high OFF-current value. When using a thin film transistor
